STRONG MONOTONICITY OF SPECTRAL RADIUS OF POSITIVE OPERATORS.

DONALD W. HADWIN, ARKADY K. KITOVER, AND MEHMET ORHON

Abstract. The classic result of Perron and Frobenius states that if A and B are matrices with nonnegative elements, such that $A \leq B$, A is irreducible, and $\rho(A) = \rho(B)$ then $A = B$. We extend this result to a large class of band irreducible positive operators on a large class of Banach lattices and provide examples to show that the conditions we put on the operators and the Banach lattices cannot be weakened.

A part of the famous Perron - Frobenius theorem states that if A and B are matrices with nonnegative elements, such that $A \leq B$, A is irreducible, and $\rho(A) = \rho(B)$ where $\rho(A)$ means the spectral radius of A then $A = B$. It was proved by Perron in [23] in 1907 for matrices with strictly positive elements and by Frobenius in [11] in 1912 for arbitrary irreducible matrices. The proof can be also found in [26, Section 2.1]. While the part of Perron - Frobenius theorem which describes the structure of peripheral spectrum of nonnegative irreducible matrices became a subject of very active research and was successively extended to include the class of band irreducible positive compact operators on Banach lattices (an extensive bibliography can be found in [13] and in [1]) the above statement about spectral radii until recently attracted comparatively less attention.

Nevertheless in 1970 Marek [21, Theorem 4.3] proved the following very general result.

Theorem 1. *(Marek [21]) Let X be a partially ordered Banach space with the closed normal B-cone K. Let T_1, T be positive linear operators on X, $T_1 \leq T$, and T be semi non-supporting. Let $\rho(T)$ be an eigenvalue of T and the Banach conjugate operator T' to which correspond a positive eigenvector and respectively a positive eigenfunctional. Let also $\rho(T_1)$ be an eigenvalue of T_1' with a positive eigenfunctional. Finally assume that $\rho(T) = \rho(T_1)$. Then $T = T_1$.*

Key words and phrases. Positive operators, spectrum.

Let us discuss the meaning of conditions of Theorem 1 in the case when the partially ordered Banach space X is a Banach lattice.

The condition that the cone K is a B-cone was introduced by Sawashima in [24] and means the following:

$$\exists C > 0, \forall x \in X \exists \{x_{1n}\}_{n\in\mathbb{N}}, \{x_{2n}\}_{n\in\mathbb{N}} \subset K \text{ such that } x_{1n} - x_{2n} \underset{n\to\infty}{\to} x$$

$$\text{and } \|x_{in}\| \leq C\|x\|, i = 1, 2, n \in \mathbb{N}.$$

This condition is obviously satisfied for the cone of positive elements in a Banach lattice.

The condition that an operator T is semi non-supporting was also introduced in [24] and means that for any nonzero $x \in K$ and x' in K' there is a $p = p(x, x') \in \mathbb{N}$ such that $(T^p x, x') > 0$. In the case of Banach lattices this condition is well known to be equivalent to T being ideal irreducible. For the sake of completeness we provide a short proof.

Proposition 2. *Let T be a positive operator on a Banach lattice X. Then T is semi non-supporting if and only if it is ideal irreducible.*

Proof. Assume first that there is a nontrivial closed ideal J in X such that $TJ \subseteq J$. Then the annihilator of J is a nontrivial band in X' and therefore there is a positive nonzero $x' \in X'$ such that $x'(J) = 0$. Let $x \in J$ be positive and nonzero. Then $(T^p x, x') = 0, p \in \mathbb{N}$ whence T is not semi non-supporting.

Next assume that there are positive nonzero $x \in X$ and $x' \in X'$ such that $(T^p x, x') = 0, p \in \mathbb{N}$. Let $z = \sum \frac{T^n x}{2^n \|T^n x\|}$ where the sum is taken over all $n \in \mathbb{N}$ such that $T^n x \neq 0$. Then the closed principal ideal generated by z is T-invariant and nontrivial. ☐

Thus Theorem 1 provides a very satisfactory extension of the corresponding part of the Perron - Frobenius theorem for the ideal irreducible operators. Our goal in this paper is to obtain a similar extension for the larger class of **band irreducible** operators.

In fact, in the case when the Banach lattice X has order-continuous norm every closed ideal is a band and there is nothing to prove. But, as the next example shows, for an arbitrary Banach lattice we cannot just substitute band irreducible for ideal irreducible in the conditions of Theorem 1.

Example 3. Let $X = \{x \in C[0,1] \ : \ x(0) = x(1)\}$. Clearly X is a Banach lattice. Let α be an irrational number from $(0,1)$. By $t \dotplus \alpha$ we will mean addition modulo 1. Let $l \in X$ such that $l(1/2) = 0$, $l(t) > 0$, if $t \in [0,1]$ and $t \neq 1/2$, and $\int\limits_0^1 \ln l(t)dt = -\infty$. For example we can take

$$l(t) = \begin{cases} e^{-\frac{1}{(t-1/2)^2}}, & \text{if } t \neq 1/2, \\ 0, & \text{if } t = 1/2 \end{cases}$$

We introduce the following positive operators.

$$(Ax)(t) = x(1/2), x \in X, t \in [0,1],$$
$$(Bx)(t) = l(t)x(t \dot{+} \alpha), x \in X, t \in [0,1],$$
$$C = A + B.$$

It is obvious that the operator A is one dimensional and that its spectrum $\sigma(A) = \{0,1\}$. The operator B is band irreducible because α is an irrational number. Moreover the condition $\int\limits_0^1 \ln l(t)dt = -\infty$ guarantees that B is quasinilpotent (see e.g., [9]). Next notice that $\rho(C) \geq \rho(A) = 1$ and that because C is a positive operator $\rho(C) \in \sigma(C)$. The operator C is a compact perturbation of B. Clearly the Fredholm [1] spectrum of B, $\sigma_f(B)$, is the singleton $\{0\}$. The Fredholm spectrum does not change under compact perturbations (see [16, Theorem 5.35, p.244]) whence $\sigma_f(C) = \{0\}$ and by [16, Theorem 5.33, p. 243] $\rho(C)$ is an isolated point and an eigenvalue of C of finite multiplicity. We claim that $\rho(C) = 1$. Indeed, assume to the contrary that $\rho(C) = r > 1$. Let $z \in X$ be the corresponding eigenvector. Then

$$l(t)z(t \dot{+} \alpha) + z(1/2) = rz(t),\ t \in [0,1]$$

Because $l(1/2) = 0$ we see that $z(1/2) = 0$ whence $l(t)z(t \dot{+} \alpha) = rz(t),\ t \in [0,1]$ in contradiction to B being quasinilpotent.

We claim additionally that the spectral projection corresponding to the isolated eigenvalue 1 is one dimensional. Indeed, assume first that there are two linearly independent eigenvectors f and g of C corresponding to the eigenvalue 1. Then $f(1/2) \neq 0$ and $g(1/2) \neq 0$. Therefore, without loss of generality we can assume that $f(1/2) = g(1/2)$. But then $B(f-g) = f-g$ whence $f = g$, a contradiction.

Assume now that f is an eigenvector of C corresponding to the eigenvalue 1, and that h is a root vector of C, i.e. $(I-C)h = f$. Then

$$l(t)h(t \dot{+} \alpha) + h(1/2) - h(t) = f(t), t \in [0,1].$$

If we put $t = 1/2$ in the above equation we get $f(1/2) = 0$ whence $Bf = f$, a contradiction again.

---

[1] As usual we understand by Fredholm spectrum of a bounded operator on a Banach space its spectrum in the Calkin algebra.

Now we see that there is a positive eigenvector of C corresponding to the eigenvalue 1. Indeed, because the spectral projection P on the eigenspace of C corresponding to the eigenvalue 1 is one dimensional we can apply the well known formula

$$P = \lim_{r \to 1+} (r-1) \sum_{n=0}^{\infty} \frac{C^n}{r^{n+1}} \tag{$\bigstar$}$$

(see e.g., [25, p. 329]), that shows that P is a positive operator.

Similar reasoning applied to the Banach dual operators A', B', and C' shows that $\rho(C') = 1$ and 1 is an eigenvalue of C' to which corresponds a positive eigenfunctional (notice that the spectral projection on the eigenspace of C' corresponding to the eigenvalue 1 coincides with P' and therefore is one dimensional).

Thus we see that the operators A and C satisfy all the conditions of Theorem 1 with the exception that instead of being ideal irreducible C is only band irreducible (clearly C leaves invariant the ideal $I = \{x \in X : x(1/2) = 0\}$), but exactly because of this exception the statement of the said theorem is not true anymore.

A quick look at Example 3 allows us to notice the reason for this failure; the operators A and C are not order continuous. Indeed, Alekhno (see [5, Theorem 5]) proved that the conclusion of Theorem 1 remains true under the assumption that the Banach lattice X has a separating set of order continuous functionals and the dominating operator T_1 is band irreducible and σ-order continuous (see Definition 4).

The main result of the current paper (Theorem 9, part (a)) extends Alekhno's result to the much larger class of Banach lattices having the property that the sequential Lorentz seminorm (see Definition 6) is a norm. Example 11 shows that this is as far as we can go.

We need to recall two definitions.

Definition 4. (See e.g., [1, Page 19]). A positive operator T on a Banach lattice X is called σ-order continuous if for every sequence $\{x_n\} \subset X$ such that $x_n \downarrow 0$ we have $Tx_n \downarrow 0$.

Remark 5. There are different definitions of σ-order continuity for operators on vector lattices but in the case of positive operators they all are equivalent to Definition 4. We refer the reader to [19] for a detailed discussion of this question.

Definition 6. Let X be a Banach lattice. The sequential Lorentz seminorm l on X is defined as

$$l(x) = \inf_{x_n \uparrow |x|} \lim_n \|x_n\|, x \in X \tag{$\star$}$$

where inf is taken over all the sequences $\{x_n\} \subset X$ such that $x_n \geq 0$ and $x_n \uparrow |x|$.

Remark 7. The class of Banach lattices X for which the sequential Lorentz seminorm is actually a lattice norm on X is very large. For example it includes all the Banach lattices with the weak sequential Fatou property (i.e., there is a constant $K \geq 1$ such that $x_n \uparrow x \Rightarrow \|x\| \leq K \sup_n \|x_n\|$ (see [2, p.89])) as well as all Banach Lattices with a separating set of σ-order continuous functionals. Important examples are provided by the Banach spaces of measurable functions.

We will need the following lemma.

Lemma 8. *Let X be a Banach lattice such that $dim X > 1$. Let $T : X \to X$ be a positive, band-irreducible, and σ-order continuous operator such that its spectral radius $\rho(T)$ is a pole of the resolvent $R(\lambda, T)$.*

Assume additionally at least one of the following two conditions:

(a) The sequential Lorentz semi-norm l is a norm on X;

(b) The operator T is weakly compact.

Then $\rho(T) > 0$, the multiplicity of the pole $\rho(T)$ is 1, the corresponding eigenspace is one dimensional, and the spectral projection P_T is σ-order continuous.

Proof. The inequality $\rho(T) > 0$ follows trivially from the fact that T is band irreducible (see [17]).

It was proved in [17, Theorem 6 and Lemmas 7 and 8] that the conditions in part (a) imply the conclusion of the lemma.

To prove the conclusion of the lemma in case part (b) holds, assume that $\rho(T) = 1$. Let p be the order of the pole at 1 and let $Q_{-p} = \lim_{\lambda \downarrow 1} (\lambda - 1)^p R(\lambda, T)$ where the limit is in operator norm. Notice that the operator Q_{-p} is positive and commutes with T. If we prove that Q_{-p} is σ-order continuous then we can repeat arguments from the proof of Theorem 6 in [17] and finish the proof. Assume to the contrary that there is a sequence $x_n \in X$, $n \in \mathbb{N}$ such that $x_n \downarrow 0$ but $Q_{-p} x_n \geq y \gneqq 0$. Notice that $T x_n \downarrow 0$ and T is weakly compact whence $T x_n$ weakly converges to 0. Therefore $Q_{-p} T x_n$ weakly converges to 0. But $Q_{-p} T x_n = T Q_{-p} x_n \geq T y$ whence $T y = 0$. Therefore $T\{y\}^{dd} = 0$ in contradiction to T being band irreducible. □

Now we can state and prove our main result.

Theorem 9. *Let X be a Banach lattice, A and B be positive operators on X such that $A \leq B$, B is band irreducible, and $\rho(A) = \rho(B) > 0$. Assume additionally that at least one of the following conditions is satisfied.*

(a) The sequential Lorentz seminorm l is a norm on X, B is σ-order continuous, and $\rho(B)$ is a pole of the resolvent $R(\lambda, B)$.
(b) The sequential Lorentz seminorm l is a norm on X, B is σ-order continuous, $\rho(A)$ is a pole of the resolvent $R(\lambda, A)$, and the corresponding spectral subspace of A is finite dimensional.
(c) The operator B is weakly compact, σ-order continuous, and $\rho(B)$ is a pole of the resolvent $R(\lambda, B)$.
(d) The operator A is band irreducible, weakly compact, and $\rho(A)$ is a pole of the resolvent $R(\lambda, A)$. The operator B is σ-order continuous.

Then $A = B$.

Proof. Part (a). By part (a) of Lemma 8 we have $\rho(B) > 0$ and the corresponding eigenspace is one dimensional. Let P be the corresponding spectral projection. Without loss of generality we can assume that $\rho(B) = 1$. For a positive ε let $B_\varepsilon = \varepsilon A + (1-\varepsilon)B$. Notice that $A \leq B_\varepsilon \leq B$ and therefore $\rho(B_\varepsilon) = 1$. Then (see [10, Lemma VII.6.8]) for a small enough ε the point 1 will be an isolated eigenvalue of B_ε of multiplicity 1. Let Q be the corresponding spectral projection. The formula ($\bigstar$) applied to the projection Q provides $Q = \lim\limits_{\lambda \downarrow 1}(\lambda - 1)\sum\limits_{n=0}^{\infty} \frac{(B_\varepsilon)^n}{\lambda^{n+1}}$ whence $Q \geq 0$ and therefore there is $g \in X$, $g \gneqq 0$, and $B_\varepsilon g = g$.

Next we notice that $Bg \geq B_\varepsilon g = g$. Assume for a moment that $Bg \neq g$. The formula ($\bigstar$) and the inequality $B \geq B_\varepsilon$ guarantee that $P \geq Q$ whence $Pg \geq Qg = g$. Notice that our assumption $Bg \neq g$ implies that $Pg \neq g$ because $BPg = Pg$. Next we see that $B(Pg-g) = Pg - Bg \geq 0$ whence $Pg \geq Bg \geq g$. From the last inequality we have $-g \geq -Bg$ and therefore $Pg - g \geq Pg - Bg = B(Pg - g) \geq 0$. We see now that operator B leaves invariant the principal ideal generated by $Pg - g$ and because B is σ-order continuous it leaves invariant the nonzero principal band $\mathfrak{B}$ generated by $Pg - g$. But B is band irreducible whence $\mathfrak{B} = X$. Next notice that $P(Pg - g) = 0$ and that the operator P is positive and σ-order continuous by Lemma 8 whence $P = 0$, a contradiction.

We have just proved that $Bg = B_\varepsilon g = g$. The operator $B - B_\varepsilon$ is σ-order continuous because $0 \leq B - B_\varepsilon \leq B$ and therefore $B - B_\varepsilon$ is zero on the principal band $\mathfrak{C} = \{g\}^{dd}$ generated by g. But it follows immediately from $Bg = g$ and the fact that B is σ-order continuous that $B\mathfrak{C} \subseteq \mathfrak{C}$. Recalling that B is band irreducible we see that $\mathfrak{C} = X$ whence $B_\varepsilon = B$ and therefore $A = B$.

Part (b). Assume again that $\rho(A) = \rho(B) = 1$. For a positive ε consider the operator $B_\varepsilon = (1-\varepsilon)A + \varepsilon B$. Then $A \leq B_\varepsilon \leq B$ whence $\rho(B_\varepsilon) = 1$. Lemma VII.6.8 in [10] guarantees that for a small enough

ε, 1 is a pole of the resolvent $R(\lambda, B_\varepsilon)$. Next notice that the operator B_ε is σ-order continuous because $B_\varepsilon \leq B$. We claim that B_ε is band irreducible. Indeed, let $\mathfrak{B}$ be a nontrivial B_ε invariant band in X. Then $A\mathfrak{B} \subseteq \mathfrak{B}$ because $A \leq B_\varepsilon$. But B is a linear combination of A and B_ε whence $B\mathfrak{B} \subseteq \mathfrak{B}$ in contradiction to our assumption that B is band irreducible.

By part (a) we have $A = B_\varepsilon$ whence $A = B$.

Part (c). We can assume that $\rho(B) = 1$. Our assumptions about the operator B and part (b) of Lemma 8 guarantee that 1 is an eigenvalue of B of multiplicity one and that the corresponding one-dimensional spectral projection P is σ-order continuous. The rest of the proof is the same as in part (a).

Part (d). Assume $\rho(A) = \rho(B) = 1$. As in part (c) our assumptions guarantee that 1 is the pole of $\rho(\lambda, A)$ of multiplicity one and that the corresponding one-dimensional spectral projection P_A is σ-order continuous. Let g be the corresponding positive eigenvector. Substituting, if needed, B by $B_\varepsilon = (1-\varepsilon)A + \varepsilon B$ where ε is a small enough positive number we can assume that 1 is the pole of $\rho(\lambda, B)$ also of multiplicity one. Let P_B be the corresponding one-dimensional spectral projection. Notice that $Bg \geq Ag = g$. Assume that $Bg \gneq g$. Then exactly as in part (a), we conclude that $P_B g \geq Bg \geq g \geq 0$ and that $P_B g - g \geq B(P_B g - g) \geq A(P_B g - g) \geq 0$. Since both A and B are σ-order continuous they both leave invariant the principal band $\mathfrak{B} = \{P_B g - g\}^{dd}$. But A and B are band irreducible. Therefore $\mathfrak{B} = X$. However, since $P_B \geq P_A \geq 0$ and $P_B(P_B g - g) = 0$, we have $P_A(P_B g - g) = 0$. We already noted that Lemma 0.8 implied that P_A is σ-order continuous. Therefore $P_A(\mathfrak{B}) = P_A(X) = \{0\}$. This is a contradiction since P_A is non-zero. $\square$

Remark 10. We can further weaken the conditions in parts (c) and (d) of Theorem 9 (Compare with Theorem 6 in [17] and with [18]). Namely, in part (c) instead of assuming that B is σ-order continuous and weakly compact we can assume that there are positive operators R and S such that R is weakly compact, $S \leq R$ and $S \neq 0$, $SB \leq BS$, and either R is order continuous, or R is σ-order continuous and S is band irreducible (in connection with this see [18]). Similar changes can be made for part (d). (See the appendix.)

We will now discuss in more detail the conditions in the statement of Theorem 9.

Concerning parts(a) and (b), we showed already in Example 3 that the condition that B is σ-order continuous cannot be omitted. But to show that we cannot dispense with the condition that the sequential

Lorentz seminorm is a norm on X requires a more subtle example. For this purpose we will use and modify the example from [4, Proposition 13.5] (See also [19, Section 3]).

Example 11. There are a Banach lattice X (on which the sequential Lorentz seminorm is not a norm) and positive operators A and B on X such that

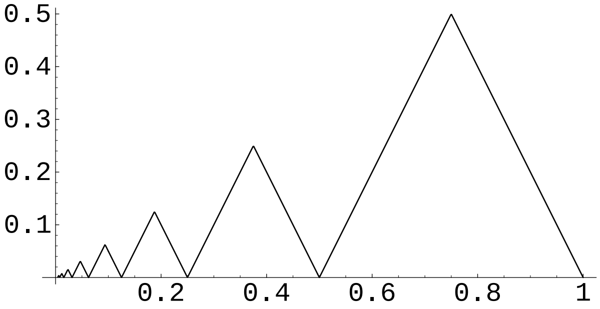
- $0 \leq A \leq B$.
- $\rho(A) = \rho(B) = 1$.
- $\rho(B)$ is a pole of the resolvent $R(\lambda, B)$ of multiplicity one.
- B is order continuous.
- B is band irreducible.

However, $A \neq B$.

Proof. Part 1. In this part we will construct the Banach space X and the operator A. Let ψ_0 denote a function on $[0,1]$ defined as follows:

$$\psi_0(t) = \begin{cases} 2t & \text{if } t \in [0,1/2], \\ 2-2t & \text{if } t \in [1/2,1], \end{cases}$$

Using this function ψ_0, we define a mapping $\psi : [0,1] \to [0,1]$ by letting $\psi(0) = 0$ and letting $\psi(t) = 2^{-n}\psi_0(2^n t - 1)$ for $t \in [2^{-n}, 2^{-n+1}]$ and $n \in \mathbb{N}$. The graph of ψ is shown below.



Next we define the mapping $\varphi : [0,2] \to [0,2]$ by letting

$$\varphi(t) = \begin{cases} \psi(t) & \text{if } t \in [0,1], \\ \psi(2-t) & \text{if } t \in [1,2], \end{cases}$$

We introduce the composition operator T_φ on $C[0,2]$ by the formula $T_\varphi f = f \circ \varphi$, $f \in C[0,2]$. We will describe recursively the sets $\varphi^{-n}(0)$, $n \in \mathbb{N}$. Clearly $\varphi^{-1}(0) = \{0\} \cup \{1/2^k, \ k \in \mathbb{N}\} \cup \{1\} \cup \{2 - 1/2^k, k \in \mathbb{N}\} \cup \{2\}$. Let $n \in \mathbb{N}$ and let (a,b) be an interval complementary to $\varphi^{-n}(0)$ (i.e. $a, b \in \varphi^{-n}(0)$ and $(a,b) \cap \varphi^{-n}(0) = \emptyset$).

Then

$$(a,b)\cap\varphi^{-(n+1)}(0)=\{\frac{(2^k-1)a+b}{2^k}:k\in\mathbb{N}\}\cup\{\frac{a+(2^k-1)b}{2^k}:k\in\mathbb{N}\} \tag{$\star\star\star$}$$

.

From the description above it is easy to see that the mapping φ has the following properties:

(1) For any $n\in\mathbb{N}$, 0 is the only fixed point of the mapping φ^n whence $\varphi^{-n}(0)\subset\varphi^{-(n+1)}(0),\ n\in\mathbb{N}$.
(2) For any $n\in\mathbb{N}$, the set $\varphi^{-n}(0)$ is countable.
(3) The set $\bigcup\limits_{n=1}^{\infty}\varphi^{-n}(0)$ is dense in $[0,2]$.

We introduce a lattice seminorm $|||\cdot|||$ on $C[0,2]$ as follows:

$$|||f|||=\sup_{n\in\mathbb{N}}\{\frac{1}{n!}\max_{t\in\varphi^{-n}(0)}|f(t)|\} \tag{$\star\star$}$$

The condition (3) above guarantees that this lattice seminorm is actually a norm on $C[0,2]$. Let X be the completion of $C[0,2]$ in this norm. Then X is a Banach lattice. Notice that the Lorentz seminorm on X is not a norm (see Lemma 12 below). The obvious inequality $|||T_\varphi f|||\le|||f|||, f\in C[0,2]$ shows that T_φ can be extended as a continuous operator on X. We will denote the extension by A. Thus A is a positive operator on X and $\|A\|\le 1$. Moreover, the operator A preserves disjointness and therefore it is a lattice homomorphism.

Part 2. We will prove here that the spectrum of A on X is the set $\{0,1\}$ and that 1 is an eigenvalue of A of multiplicity 1. Indeed, the space X is the direct sum of the closed ideal J, $J=\{x\in X:x(0)=0\}$ and the one-dimensional subspace Y generated by the function $\mathbb{1}$. Notice that $AY=Y$ and $AJ\subset J$. Let $x\in J$ and $k\in\mathbb{N}$, then

$$|||A^kx|||=\sup_{n\in\mathbb{N}}\{\frac{1}{n!}\max_{t\in\varphi^{-n}(0)}|x(\varphi^k(t))|\}.$$

But because $x\in J$ we have $A^kx\equiv 0$ on $\varphi^{-k}(0)$ and therefore

$$|||A^kx|||=\sup_{n\ge k+1}\{\frac{1}{n!}\max_{t\in\varphi^{-n}(0)}|x(\varphi^k(t))|\}\le$$

$$\sup_{n\ge k+1}\{\frac{1}{n!}\max_{t\in\varphi^{-n+k}(0)}|x(t)|\}\le\sup_{n\ge k+1}\{\frac{1}{k!(n-k)!}\max_{t\in\varphi^{-n+k}(0)}|x(t)|\}\le$$

$$\frac{1}{k!}|||x|||.$$

Hence, the restriction $A|J$ is a quasinilpotent operator.

Part 3. We claim that the operator A is order continuous. Let us consider $E = \bigcup\limits_{n=1}^{\infty} \varphi^{-n}(0)$ as a topological space with the topology of inductive limit. Then every $x \in X$ can be represented as a continuous function on E and the principal ideal (not closed!) I in X generated by $\mathbb{1}$ can be identified with the space of all bounded continuous functions on E. By the Kreins'-Kakutani theorem the ideal I is order isomorphic to $C(K)$ for some compact Hausdorff space K. We see that K is homeomorphic to the Stone - Čech compactification βE of E. [2] Next notice that $AI \subset I$ and that the operator A induces a homomorphism of the algebra $C(\beta E)$ to which corresponds a continuous mapping τ of βE into itself. It is easy to see that τ is the unique extension of the map $\varphi : E \to E$ on βE (see Lemma 13).

It follows from the definition of φ that if U is a subset of $[0, 2]$ and $IntU \neq \emptyset$ then $Int\varphi(U) \neq \emptyset$. The definition of the inductive limit topology on E shows that the map $\varphi : E \to E$ has the same property (see the proof of Lemma 13). Recall that E is a completely regular topological space and as such is dense in βE. Therefore τ being the extension of φ also maps a set with with nonempty interior to a set with nonempty interior (Lemma 13). Hence by Lemma 14 below, $A|I$, the restriction of A to the ideal generated by $\mathbb{1}$ in X, is order continuous. From this it follows easily that A is order continuous. Indeed, assume to the contrary that there exist a net $x_\alpha \downarrow 0$ and a $z \in X$, $z \gneqq 0$ such that $Ax_\alpha \geq z$. But then $x_\alpha \wedge \mathbb{1} \downarrow 0$ and $A(x_\alpha \wedge \mathbb{1}) = Ax_\alpha \wedge A\mathbb{1} \geq z \wedge A\mathbb{1} = z \wedge \mathbb{1} \gneqq 0$ (we have used here that A is lattice homomorphism, $A\mathbb{1} = \mathbb{1}$, and $\mathbb{1}$ is a weak unit in X) in contradiction to $A|I$ being order continuous.

Part 4. Here we will construct the operator B. We need first to construct a sequence of auxiliary operators on X. To do it we will need the description of the sets $\varphi^{-n}(0)$, $n \in \mathbb{N}$, from Part 1. The open subintervals of $[0, 2]$ complementary to $\varphi^{-1}(0)$ and ordered according to their natural order on the real line make an infinite sequence $\{I_n\}_{n \in \mathbb{Z}}$ where $\mathbb{Z}$ as usual is the set of all integers and $I_0 = (1/2, 1)$. We will call these intervals - intervals of the first order. Let us define a homeomorphism θ_1 of $[0, 2]$ onto itself as follows: θ_1 maps the closure of every interval I_n onto the closure of its neighbor to the right, I_{n+1}, $n \in \mathbb{Z}$, θ_1 is linear on the closure of each I_n, $\theta_1(0) = 0$ and $\theta_1(2) = 2$.

Now let us consider the set $\varphi^{-2}(0)$. It contains of course all the points from $\varphi^{-1}(0)$ but also inside every interval of the first order it has a countable number of new points which accumulate only to the ends of that interval (see $(\star\star\star)$). Thus inside each interval of the first order we have a countable sequence of intervals which we call intervals of the second order. Next we construct the homeomorphism θ_2 of $[0,2]$ onto itself with the following properties

---

[2] 'In order to keep the flow of the proof we delay the verification of this statement and some others to Lemma 13.

- θ_2 leaves the closure any interval of the first order invariant.
- θ_2 maps the closure of every interval of the second order onto the closure of its neighbor to the right.
- θ_2 is linear on the closure of each interval of the second order.
- $\theta_2(0) = 0$ and $\theta_2(2) = 2$.

Continuing this way we construct a sequence $\{\theta_n\}$ of homeomorphisms of $[0,2]$. The description of the sets $\varphi^{-n}(0)$ and the fact that the homeomorphism θ_k leaves the set $\varphi^{-(k-1)}(0)$ invariant and maps *linearly* every complementary interval of $\varphi^{-k}(0)$ onto its neighbor to the right allow us to conclude that $\theta_i(\varphi^{-n}(0)) = \varphi^{-n}(0), i, n \in \mathbb{N}$. Thus (recall the definition $(\star\star)$ of the norm on X) for any $i \in \mathbb{N}$ the composition operator $T_i : T_i x(t) = x(\theta_i(t)), x \in X, t \in \bigcup\limits_{n=1}^{\infty} \varphi^{-n}(0)$ is a positive disjointness preserving isometry of X onto itself. This isometry is obviously invertible; the inverse isometry is also positive. Therefore T_i is a lattice isomorphism of X onto itself and as such it is order continuous.

Let

$$T = \sum_{n, j_1, \dots j_n \in \mathbb{N}, i_1, \dots, i_n, \in \mathbb{Z}} \varepsilon_{i_1, \dots, i_n, j_1, \dots j_n} T_{j_1}^{i_1} \dots T_{j_n}^{i_n}$$

where the strictly positive numbers $\varepsilon_{i_1, \dots, i_n, j_1, \dots j_n}$ are chosen so small that the series above converges in operator norm. Because all the terms of the series are positive order continuous operators the operator T is also positive and order continuous (see [19, Proposition 2.13]).

We claim that the operator T is band irreducible. Indeed, assume to the contrary that there is a nontrivial T-invariant band $\mathfrak{B}$ in X. Recalling that if $x \in X$ and $x \equiv 0$ on $\bigcup\limits_{n=1}^{\infty} \varphi^{-n}(0)$ then $x = 0$ we see that there are an $N \in \mathbb{N}$ and two points $u_0, t \in \varphi^{-N}(0)$ such that

- u_0 and t are isolated points of $\varphi^{-N}(0)$.
- $x(u_0) = 0$ for any $x \in \mathfrak{B}$.
- There is a $z \in \mathfrak{B}$ such that $z(t) \neq 0$.

The construction of the mappings $\theta_i,\ i \in \mathbb{N}$, shows that there is an integer $i_1 \in \mathbb{Z}$ such that the points $u_1 = \theta_1^{i_1}(u_0)$ and t belong to the same subinterval of $[0,2]$ of the first order. Next we can find another integer $i_2 \in \mathbb{Z}$ such that the points $u_2 = \theta_2^{i_2}(u_1)$ and t are in the same interval of order 2. Continuing this way we will the integers $i_1, \dots, i_{N-1}$

such that the points $u_{N-1} = \theta_{N-1}^{i_{N-1}} \circ \ldots \circ \theta_1^{i_1}(u_0)$ and t are in the same interval J of order $N-1$ and, being isolated points of $\varphi^{-N}(0)$ they are endpoints of some subintervals of J of order N. The mapping θ_N shifts these intervals to the right and thus we can find the integer $i_N \in \mathbb{Z}$ such that $\theta_N^{i_N}(u_{N-1}) = t$.

Let $S = T_1^{i_1} \ldots T_N^{i_N}$. Then $Sz(u_0) = z(t) \neq 0$ whence $S\mathfrak{B} \subsetneqq \mathfrak{B}$. On the other hand the definition of the operator T shows that there is a positive constant C such that $S \leq CT$ and therefore the band $\mathfrak{B}$ must be S-invariant, which yields a contradiction.

Let l be the function $l(t) = t, t \in [0, 2]$ and L be the corresponding multiplication operator on X. Fix a positive number ε and consider $B = A + \varepsilon LT$. Then B is order continuous band irreducible positive operator on X. If ε is small enough then [16, IV.3.5] the disk $\{z \in \mathbb{C} : |z-1| \leq 1/2\}$ contains only one point of the spectrum $\sigma(B)$ and that point is an eigenvalue of B of multiplicity one. Let $\delta_0(x) = x(0), x \in X$. Then $B'\delta_0 = \delta_0$ whence $\rho(B) = 1$ and we are done. $\square$

The following three lemmas were used in the construction of Example 11. The last of them is most probably known but we were not able to find it in the literature so we provide its proof for the sake of completeness.

Lemma 12. *Let X be the Banach lattice constructed in the proof of Example 11. Then the sequential Lorentz seminorm l on X is not a norm.*

Proof. Fix $n \in \mathbb{N}$. The set $\varphi^{-n}(0)$ is a closed countable subset of $[0, 2]$ and therefore we can find a sequence $\{f_{n,k}\}_{k \in \mathbb{N}}$ of non-negative functions in $C[0, 2]$ such that $f_{n,k} \equiv 0$ on $\varphi^{-n}(0)$, $k \in \mathbb{N}$ and $f_{n,k} \underset{k\to\infty}{\uparrow} \mathbb{1}$. But the definition of norm on X (see $(\star\star)$) shows that $|||f_{n,k}||| \leq 1/(n+1)!$, $k \in \mathbb{N}$, and according to the definition of the Lorentz seminorm l (see $(\star)$) we have $l(\mathbb{1}) = 0$. $\square$

Lemma 13. *Let X be the Banach lattice constructed in the proof of Example 11 and $E = \bigcup\limits_{n=1}^{\infty} \varphi^{-n}(0)$ be the topological space endowed with the topology of inductive limit of the compact spaces $\varphi^{-n}(0)$ (considered as closed subsets of $[0, 2]$). Then the principal ideal I in X generated by the function $\mathbb{1}$, $I = \{x \in X : \exists\, c > 0$ such that $|x| \leq c\mathbb{1}\}$, is isometrically and lattice isomorphic to the space $C(\beta E)$ of all continuous functions on the Stone - Čech compactification of E. Moreover, the mapping $\varphi : E \to E$ allows the unique continuous extension $\tau : \beta E \to \beta E$ and if H is a closed subset of βE such that $Int\, H \neq \emptyset$ then $Int\, \tau(H) \neq \emptyset$.*

Proof. The definition ($\star\star$) of the norm on X shows that every $x \in X$ is a function on E, completely defined by its values on E and continuous on every set $\varphi^{-n}(0)$, $n \in \mathbb{N}$. The topology of inductive limit on E is the finest (strongest) topology on E such that every function continuous on $\varphi^{-n}(0)$, $n \in \mathbb{N}$, is continuous on E (see e.g. [15, page 44]). Therefore X is a proper subspace of $C(E)$. We claim that if f is a bounded continuous function on E then $f \in X$. Indeed, for every $n \in \mathbb{N}$ we can find a function $f_n \in C[0,2]$ such that $f_n \equiv f$ on $\varphi^{-n}(0)$ and $\|f_n\|_{C[0,2]} \leq \sup\limits_{t\in E} |f(t)|$. It is obvious from ($\star\star$) that $\{f_n\}$ is a Cauchy sequence in X and therefore converges to some $x \in X$; but $f \equiv x$ on E whence $f = x$. Now we see that the principal ideal I generated in X by the function $\mathbb{1}$ coincides with the algebra of all bounded continuous functions on E which can be identified with the space $C(\beta E)$.

To see this, it is sufficient to note that E is completely regular. In fact, let F be a closed subset of E and $t \in E \setminus F$. For some n, $t \in \varphi^{-n}(0)$. Let $f_n : \varphi^{-n}(0) \to [0,1]$ be a continuous Urysohn function such that $f_n(t) = 1$ and $f_n(\varphi^{-n}(0) \cap F) = \{0\}$. Let

$$\widetilde{f_n} : \varphi^{-n}(0) \cup (\varphi^{-(n+1)}(0) \cap F) \to [0,1]$$

be defined by

$$\widetilde{f_n}(s) = f_n(s),\ s \in \varphi^{-n}(0) \text{ and} \widetilde{f_n}(s) = 0,\ s \in (\varphi^{-(n+1)}(0) \cap F) \setminus \varphi^{-n}(0).$$

It is straight forward to show that the function $\widetilde{f_n}$ defined as above on the indicated closed subset of $\varphi^{-(n+1)}(0)$ is continuous. Then by Tietze's extension theorem there is a continuous function $f_{n+1} : \varphi^{-(n+1)}(0) \to [0,1]$ that extends $\widetilde{f_n}$. But this means it also extends f_n. Hence by induction we construct a sequence of continuous functions $\{f_n\}$ such that, for each n, $f_n : \varphi^{-n}(0) \to [0,1]$ with $f_n(t) = 1$ and $f_n(\varphi^{-n}(0) \cap F) = \{0\}$ and f_{n+1} is an extension of f_n. Now we define a function $f : E \to [0,1]$ by $f(s) = f_n(s)$ for each $s \in E$ whenever $s \in \varphi^{-n}(0)$ for some n. Clearly f is well defined and satisfies $f(t) = 1$ and $f(F) = \{0\}$. Furthermore f is continuous since $f_{|\varphi^{-n}(0)} = f_n$ is continuous for each n. Whence E is completely regular.

Returning to $C(\beta E)$ we notice that the operator T_φ is a unital homomorphism of this algebra and therefore in generates a continuous map $\tau : \beta E \to \beta E$ such that the restriction of τ on E coincides with φ. Let V be an open nonempty subset of E. The definition of inductive (or direct) limit topology (see again [15, page 44]) shows that for any $n \in \mathbb{N}$ the set $V \cap \varphi^{-n}(0)$ is an open subset of $\varphi^{-n}(0)$. Let $N \in \mathbb{N}$ be the smallest natural number such that $V \cap \varphi^{-N}(0) \neq \emptyset$. Consider the subset F of E that consists of all the points from $\varphi^{-1}(0)$ and of all the points of the form $\frac{a+b}{2}$ where $a, b \in \varphi^{-1}(0)$ and $(a, b) \cap \varphi^{(-1)}(0) = \emptyset$. We can easily see that $F \subset \varphi^{(-2)}(0)$ is a closed subset of $[0, 2]$ and of E whence $W = V \setminus F$ is open in E.

Notice that it follows from $(\star \star \star)$ that every point from $\varphi^{-N}(0)$ is limit of a sequence of points from $\varphi^{-(N+1)}(0) \setminus \varphi^{-N}(0)$. Therefore $\varphi^{-M}(0) \cap W \neq \emptyset$ where $M = \max(3, N + 1)$. Let us now fix $n \in \mathbb{N}$ such that $W_n = W \cap \varphi^{-n}(0) \neq \emptyset$. Let G be an open subset of $[0, 2] \setminus F$ such that $W_n = G \cap \varphi^{-n}(0)$. Then G is the union of disjoint open intervals (c_j, d_j), $j \in \mathbb{N}$, in $[0, 2] \setminus F$. Since $(c_j, d_j) \cap F = \emptyset$, the construction of the map φ shows that $\varphi((c_j, d_j))$ is an open subinterval of $[0, 1/2]$ (see the graph in part 1 of Example 11). Thus $\varphi(W_n) = \big(\bigcup\limits_{j=1}^{\infty} \varphi((c_j, d_j))\big) \cap \varphi^{-(n-1)}(0)$ is an open nonempty subset of $\varphi^{-(n-1)}(0)$.

We have just proved that the set $\varphi(W)$ is non-empty and open in E whence $Int\, \varphi(V) \neq \emptyset$. It remains to see that τ inherits the same property.

Let U be a non-empty open subset of βE and let $R = U \cap E$. Then $cl_E R$ has non-empty interior. Therefore $\varphi(cl_E R)$ also has non-empty interior. That is there exists a non-empty open set S in βE such that $S \cap E \subset int \varphi(cl_E R)$. But $cl_{\beta E}(S \cap E) = cl_{\beta E} S$. Now notice that $cl_E(S \cap E) \subset \varphi(cl_E R) \subset \tau(cl_{\beta E} U)$. Therefore $S \subset cl_{\beta E} S = cl_{\beta E}(S \cap E) \subset \tau(cl_{\beta E} U)$ and $int \tau(cl_{\beta E} U) \neq \emptyset$. □

Lemma 14. *Let K be a compact Hausdorff space, $\varphi : K \to K$ be a continuous mapping, and T_φ be the corresponding composition operator on $C(K)$. The following conditions are equivalent.*

1. *The operator T_φ is order continuous.*
2. *If U is a closed subset of K and $Int\, U \neq \emptyset$ then $Int\, \varphi(U) \neq \emptyset$.*

Proof. (1) ⇒ (2) Assume to the contrary that there is a closed subset U of K such that $Int\, U \neq \emptyset$ but $Int\, \varphi(U) = \emptyset$. Then we can find a net $\{f_\alpha\}$ in $C(K)$ such that $f_\alpha \downarrow 0$ and $f_\alpha = 1$ on $\varphi(U)$. Let $g \in C(K)$ be such that $g \neq 0$, *supp* $g \subset Int\, U$, and $0 \leq g \leq 1$. But then $T_\varphi f_\alpha \geq g$ in contradiction to T_φ being order continuous.

(2) ⇒ (1) Assume to the contrary that the condition (2) is satisfied but T_φ is not order continuous. Let $\{f_\alpha\}$ be a net in $C(K)$ such that $f_\alpha \downarrow 0$ and $T_\varphi f_\alpha \geq g \gneqq 0$ where $g \in C(K)$. If we fix a small enough positive ε then the set $U = \{k \in K : g(k) \geq \varepsilon\}$ is a closed subset of K and $Int\, U \neq \emptyset$. But then $f_\alpha \geq \varepsilon$ on $\varphi(U)$ and because $Int\, \varphi(U) \neq \emptyset$ we have a contradiction to $f_\alpha \downarrow 0$. □

Remark 15. Consider the operator A constructed in Example 11. The powers $A^n, n \in \mathbb{N}$, are order continuous positive operators and it can be easily seen that they converge in the operator norm to the spectral projection on the one-dimensional subspace generated by the eigenvector $\mathbb{1}$. This projection is not order continuous because its kernel is an ideal but not a band in X (it is not even σ-order continuous because the Banach lattice X is separable and every band in it is a principal band). It was proved in [19, Theorem 2.16] that if we have a Banach lattice Z and the Lorentz seminorm is a norm on Z then the operator norm limit of a sequence of order continuous positive operators is also order continuous. Therefore we see that the condition that the Lorentz seminorm is a norm cannot be omitted from the cited above theorem. The corresponding example in [19] (see [19, Section 3]) contains typing errors in its definition. It can be corrected to yield the desired result. However the proof given there needs to be corrected as well.

Now we will continue to discuss the conditions in the statement of Theorem 9 part (c). As the following example shows it is not possible to omit the condition that B is order continuous.

Example 16. We will first reproduce Example 5.1 from [3]. Let $X = M_\psi$ be a Marcinkiewicz space on $(0, 1)$ generated by the function ψ such that $\lim_{t\to 0} \frac{\psi(2t)}{\psi(t)} = 1$. Then (see [20]) there is a singular positive functional f on X such that f does not annihilate any nonzero band in X. Let e be a positive weak unit in X such that $f(e) = 0$. Then it is easy to see that the one dimensional operator T on X defined as $Tx = f(x)e, x \in X$ is band irreducible and $T^2 = 0$.

Now we can use the example above to construct the desired counterexample. Let g be a positive functional on X such that $g(e) = 1$, let $Ax = g(x)e, x \in X$ and let, $B = A+T$. Then clearly $\sigma(A) = \{0, 1\}$ whence $\rho(B) \geq 1$. But $\rho(B)$ is an eigenvalue of B and it is immediate to see that e is the only eigenvector of B corresponding to a non-zero eigenvalue, and that the corresponding eigenvalue is 1.

Remark 17. The famous theorem of de Pagter [22] states that any ideal irreducible positive compact operator has nonzero spectral radius. Thus Example 16 illustrates the difference between compact band irreducible and compact ideal irreducible operators. In connection with this example the following problem might be of independent interest.

Problem 18. *On which Banach lattices do there exist positive compact band irreducible quasinilpotent operators?*

Appendix

Proposition 19. *The condition in part (b) of Lemma 8 that the operator T is weakly compact can be substituted by the condition that T commutes with a positive weakly compact nonzero operator S and either S is order continuous or S is σ-order continuous and band irreducible. Respectively we can change the conditions in parts* (*c*) *and* (*d*) *of Theorem 9.*

Proof. As it was noticed in the proof of Lemma 8 it is enough to prove that the operator $Q_{-p} = \lim\limits_{\lambda \to 1} (\lambda - 1)^p R(\lambda, T)$ is σ-order continuous. Assume to the contrary that $x_n \downarrow 0$ but $Q_{-p}x_n \geq y \gneqq 0$. We have $Sx_n \overset{w}{\to} 0$ whence $Q_{-p}Sx_n \overset{w}{\to} 0$ and because $SQ_{-p} = Q_{-p}S$ $SQ_{-p}x_n \overset{w}{\to} 0$. But $SQ_{-p}x_n \geq Sy$ whence $Sy = 0$.

Assume first that S is order continuous. Let Z be the maximal by inclusion ideal in X such that $SZ = 0$. Then Z is a nonzero band in X. We claim that $TZ \subseteq Z$. Indeed, otherwise there are positive nonzero $z \in Z$ and $u \perp Z$ such that $Tz \geq u$. But $STz = TSz = 0$ whence $Su = 0$ in contradiction with maximality of Z. But T is band irreducible whence $Z = X$ and $S = 0$, a contradiction.

Next assume that S is σ-order continuous and band irreducible. Then $S\{y\}^{dd} = 0$ whence $\{y\}^{dd} = X$ and $S = 0$, a contradiction again. ☐

Acknowledgement. We thank E. Alekhno who read the first version of the paper (arXiv: 1205.5583) and made a number of valuable comments. Some of these have been incorporated into the present paper. In addition, three papers have recently appeared (see [6], [12], [8]) containing independently obtained results partially intersecting with our Theorem 9. We thank, respectively, E. Alekhno, V. Troitsky and N. Gao, and J. Bernik for alerting us to the respective papers.
